# Objectives

- Develop soil moisture (SM) retrieval algorithms using CYGNSS data along with ancillary datasets used by the SMAP mission processing system to produce a CYGNSS soil moisture product with the best consistency with the SMAP soil moisture;
- Leverage the established SMAP cal/val program to quantify the accuracy and spatial resolution of the CYGNSS products with error budget tables.

# Outline

- SMAP-CYGNSS Matchup
- Vegetation Dependence
- Surface Roughness Dependence
- Summary

# CYGNSS-SMAP Match Up

- CYGNSS data
  - Version 2.1
  - Level 1 data
  - Flags: Most of the quality flags are checked for
  - Excluding all Block IIF GPS s/c
- SMAP Data
  - SCAV Soil moisture < 5 kg/m<sup>2</sup>
  - Gridded NDVI VWC
  - Surface roughness (baseline and DCA h)
- CYGNSS-SMAP data match up
  - Distance: within 15 km
  - Time: within 1 day

- Assuming a radar equation for a coherent signal similar to [1]:

$$P_r^S = P_r - N = \Gamma(\theta) \frac{\lambda^2 P_t G_t G_r}{(4\pi)^2 (R_t + R_r)^2}$$

where

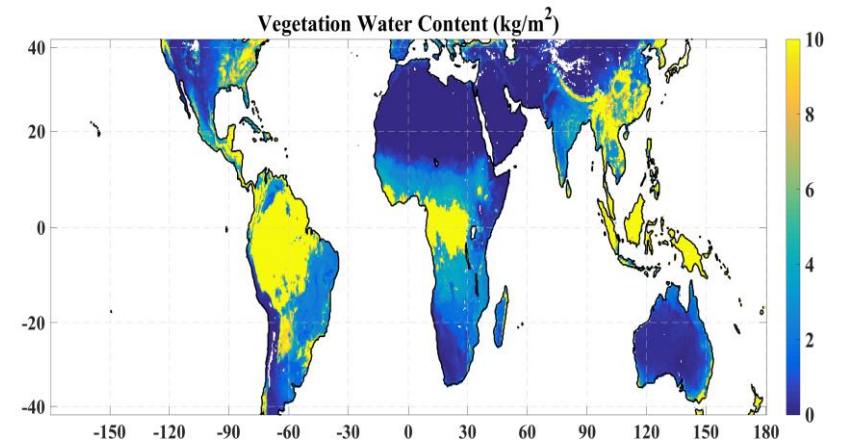

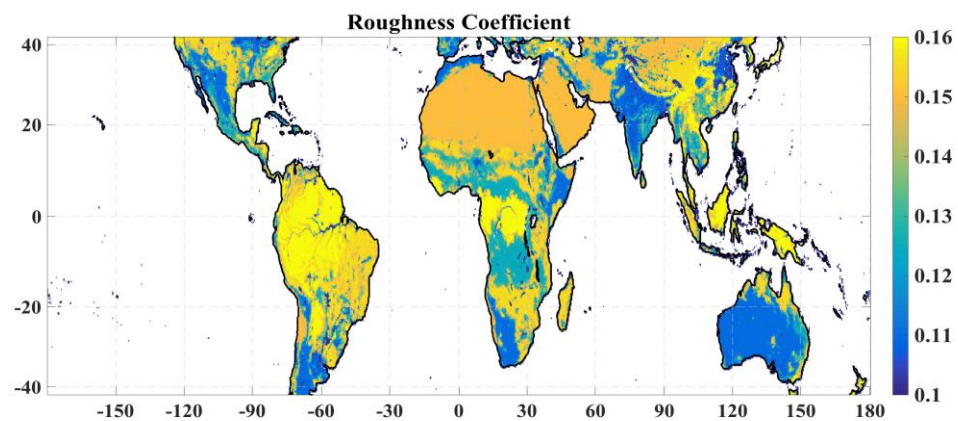

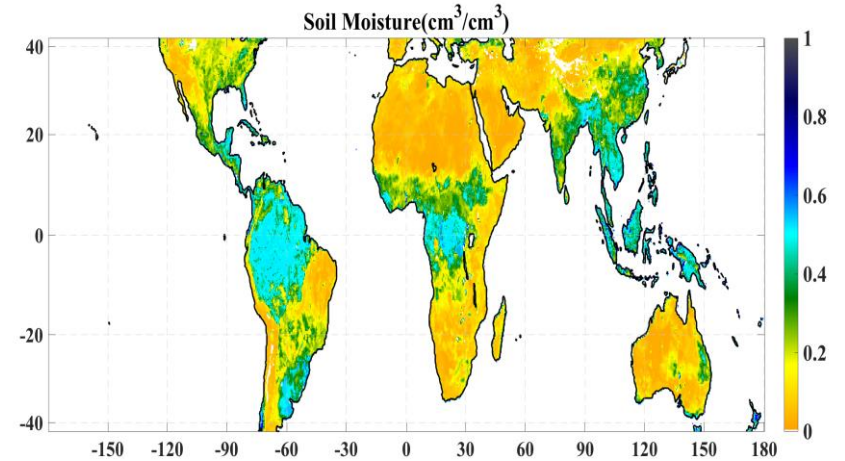

- $P_r^S$  is the received power reflected by the surface,
  - $P_r$  is the peak power of the L1 DDM of reflected power,
  - $N$  is the estimated noise floor,
  - $P_t G_t$  is GPS Equivalent Isotropically Radiated Power (EIRP),
  - $G_r$  is antenna gain towards the specular point,
  - $R_t$  is the distance between transmitter and specular point,
  - $R_r$  is the distance between receiver and specular point,
  - $\Gamma(\theta)$  is the average reflectivity, and  $\lambda$  is GPS wavelength (19 cm).
- Average reflectivity can then be computed:

$$\Gamma(\theta) = \frac{(4\pi)^2 (P_r - N) (R_t + R_r)^2}{\lambda^2 P_t G_t G_r}$$

[1] Clarizia et al., 2018

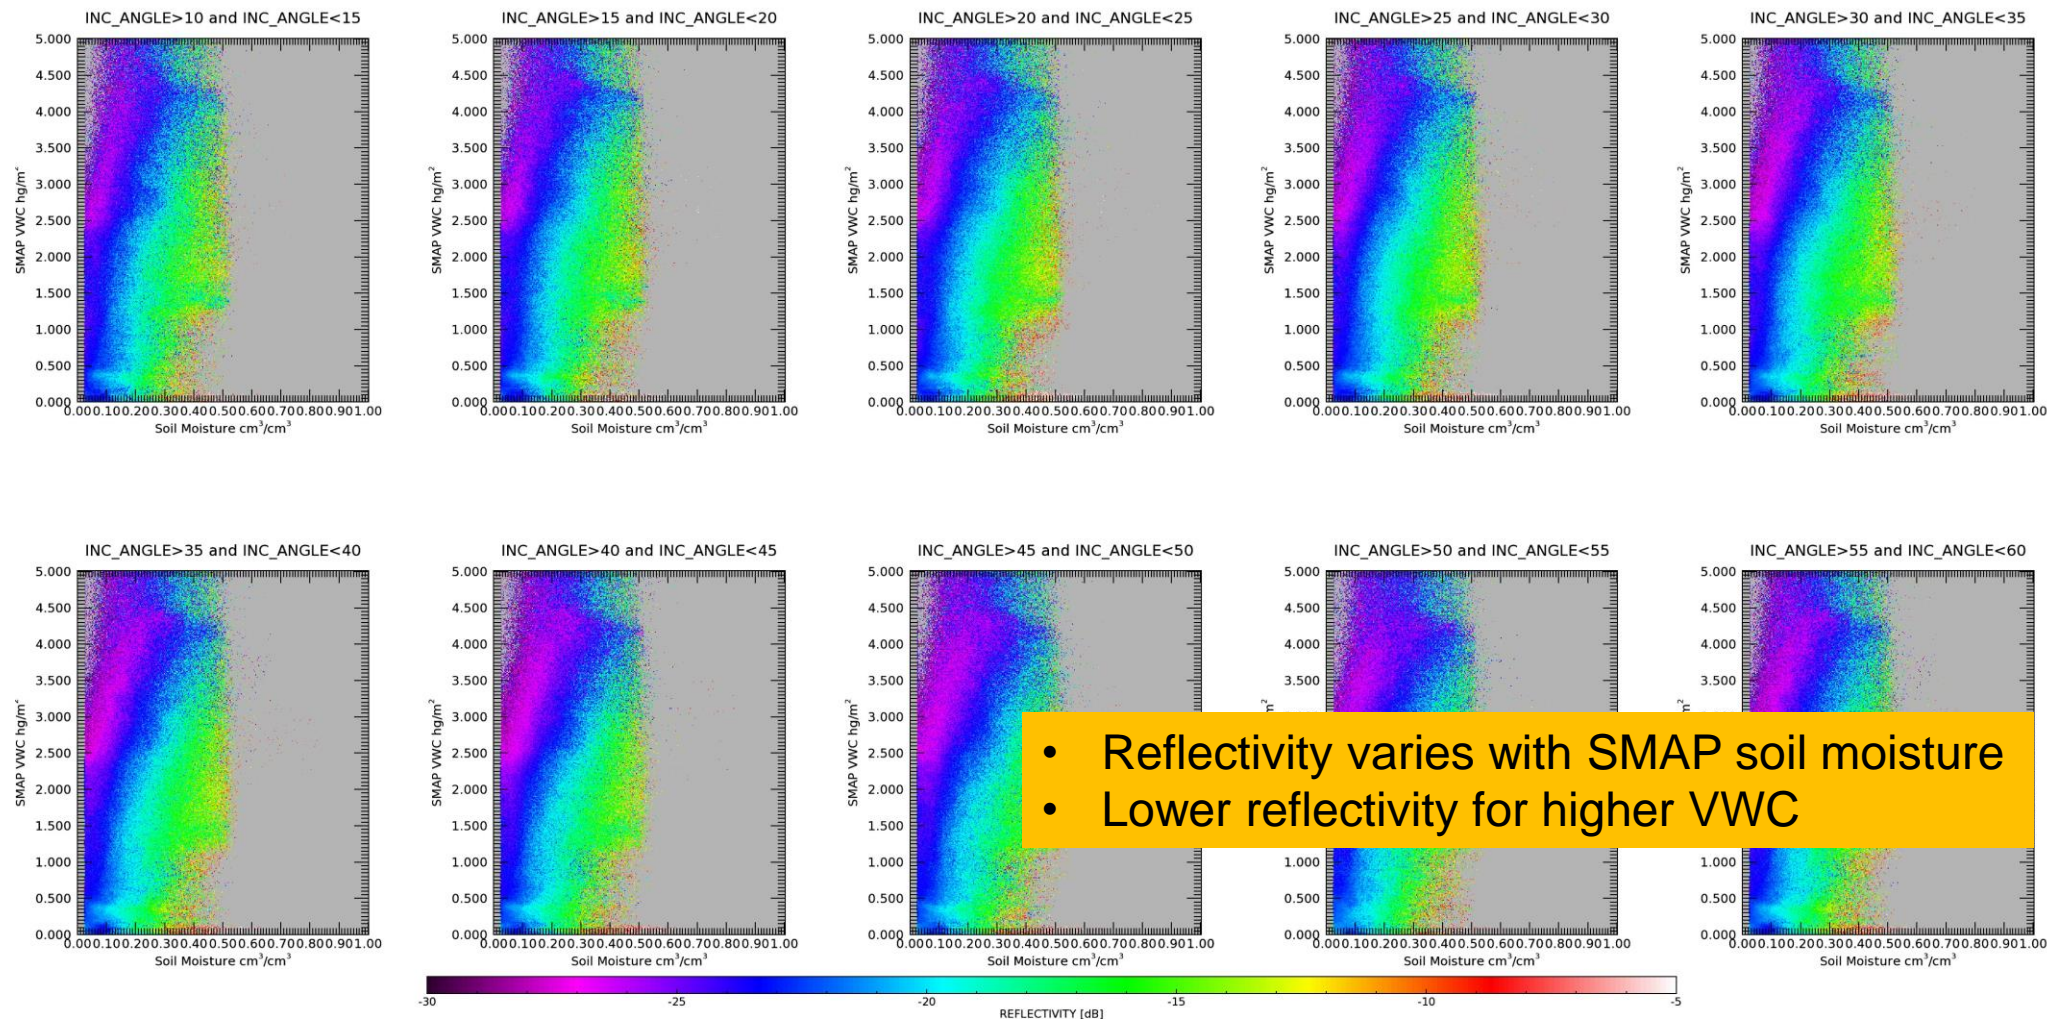

# CYGNSS Reflectivity

3-day: Sept 30-Oct 2, 2017

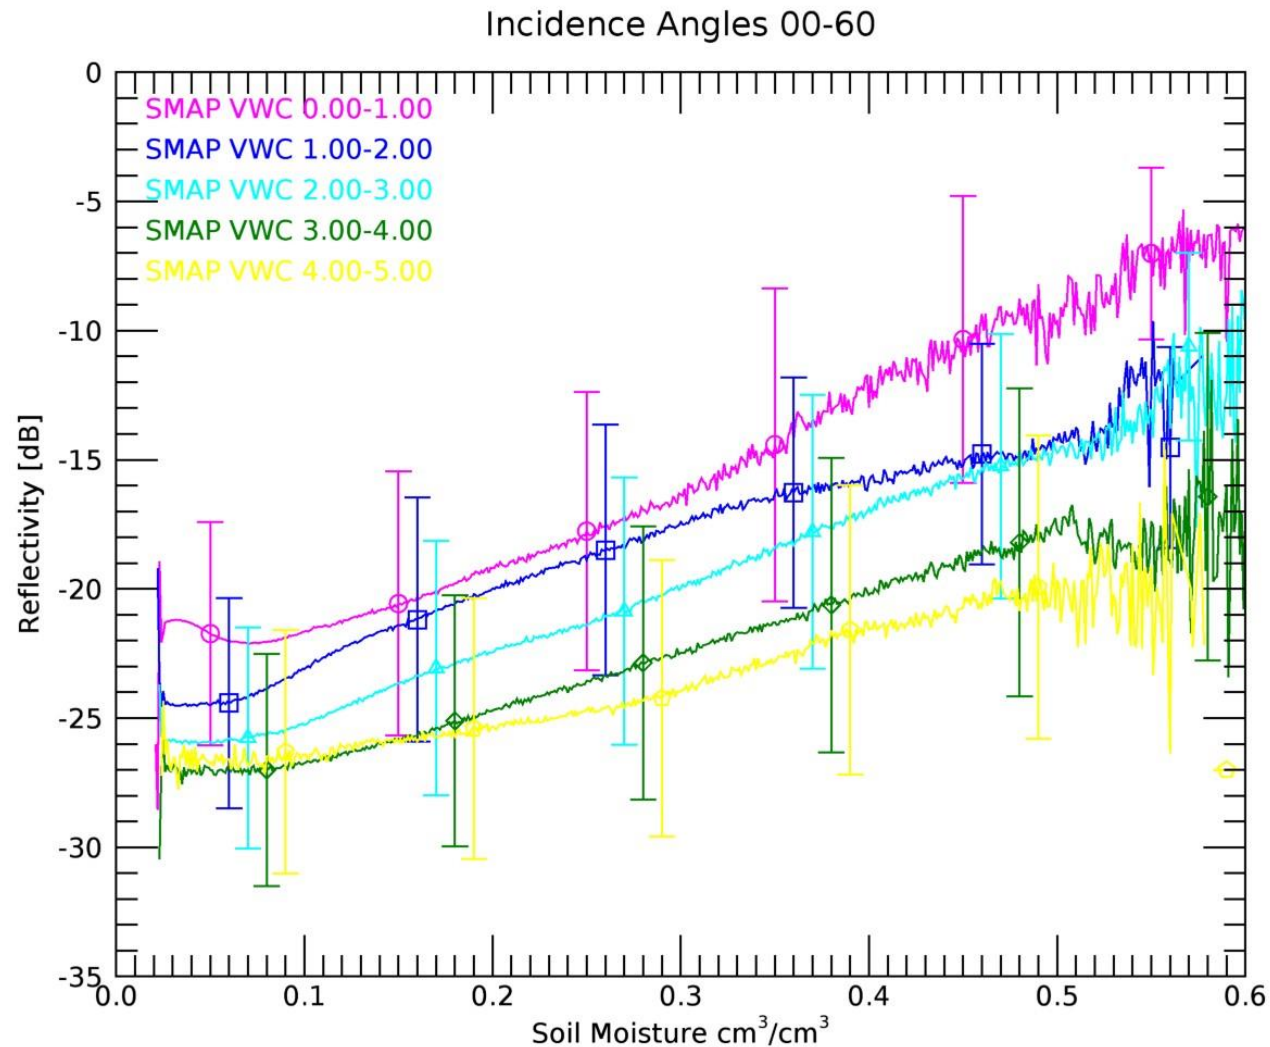

# CYGNSS Reflectivity vs. SMAP SM & VWC

## Soil Moisture for Various Incidence Angles

# Effect of VWC & Soil Moisture

# Effect of VWC & Incidence Angle

Data are stratified into every 10 degrees in incidence angles

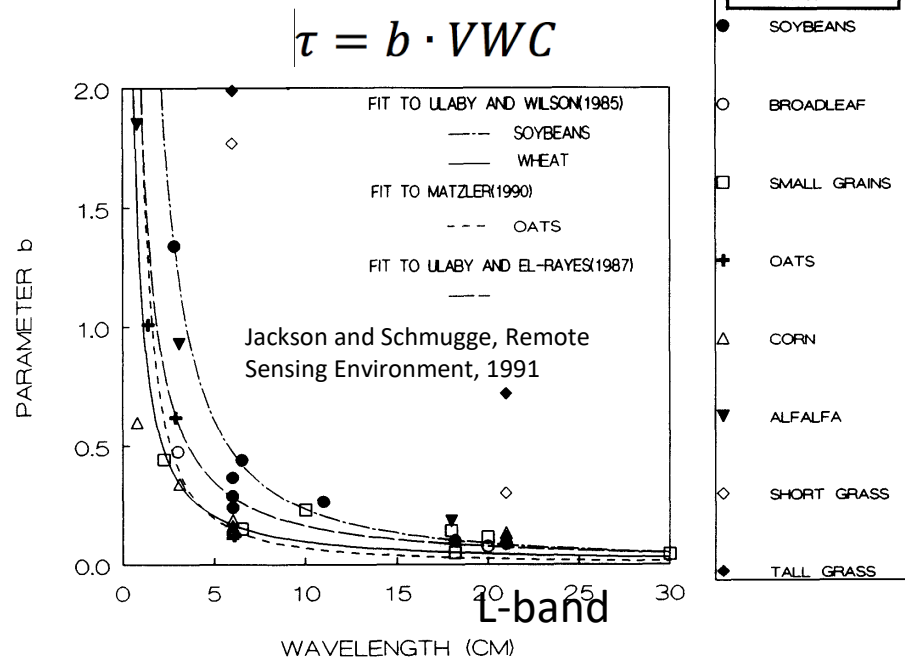

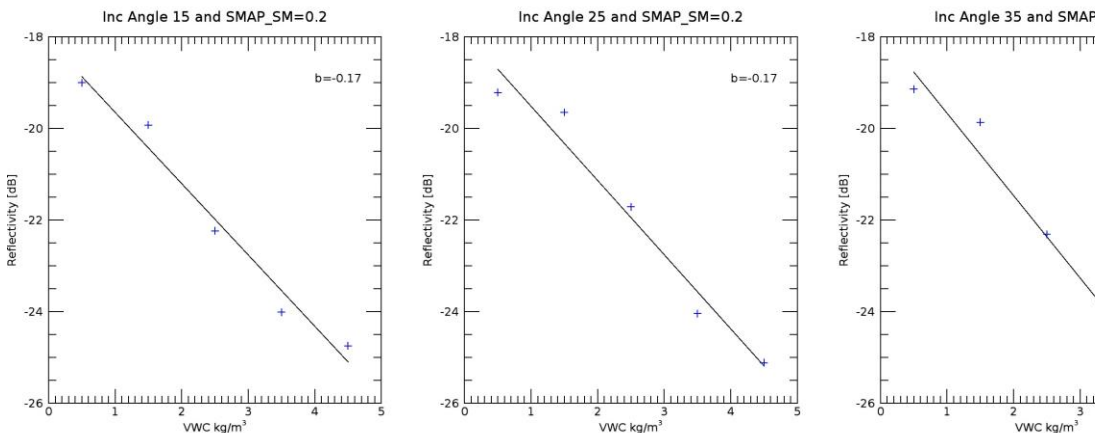

Similar features for all incidence angle bins.

# Dependence on VWC for SM of 0.2

Figure 4. Summary of experimental data of the vegetation parameter  $b$  as a function of wavelength for a variety of vegetation types.

## Excellent linear dependence

$$R_{\tau\theta} = \epsilon$$

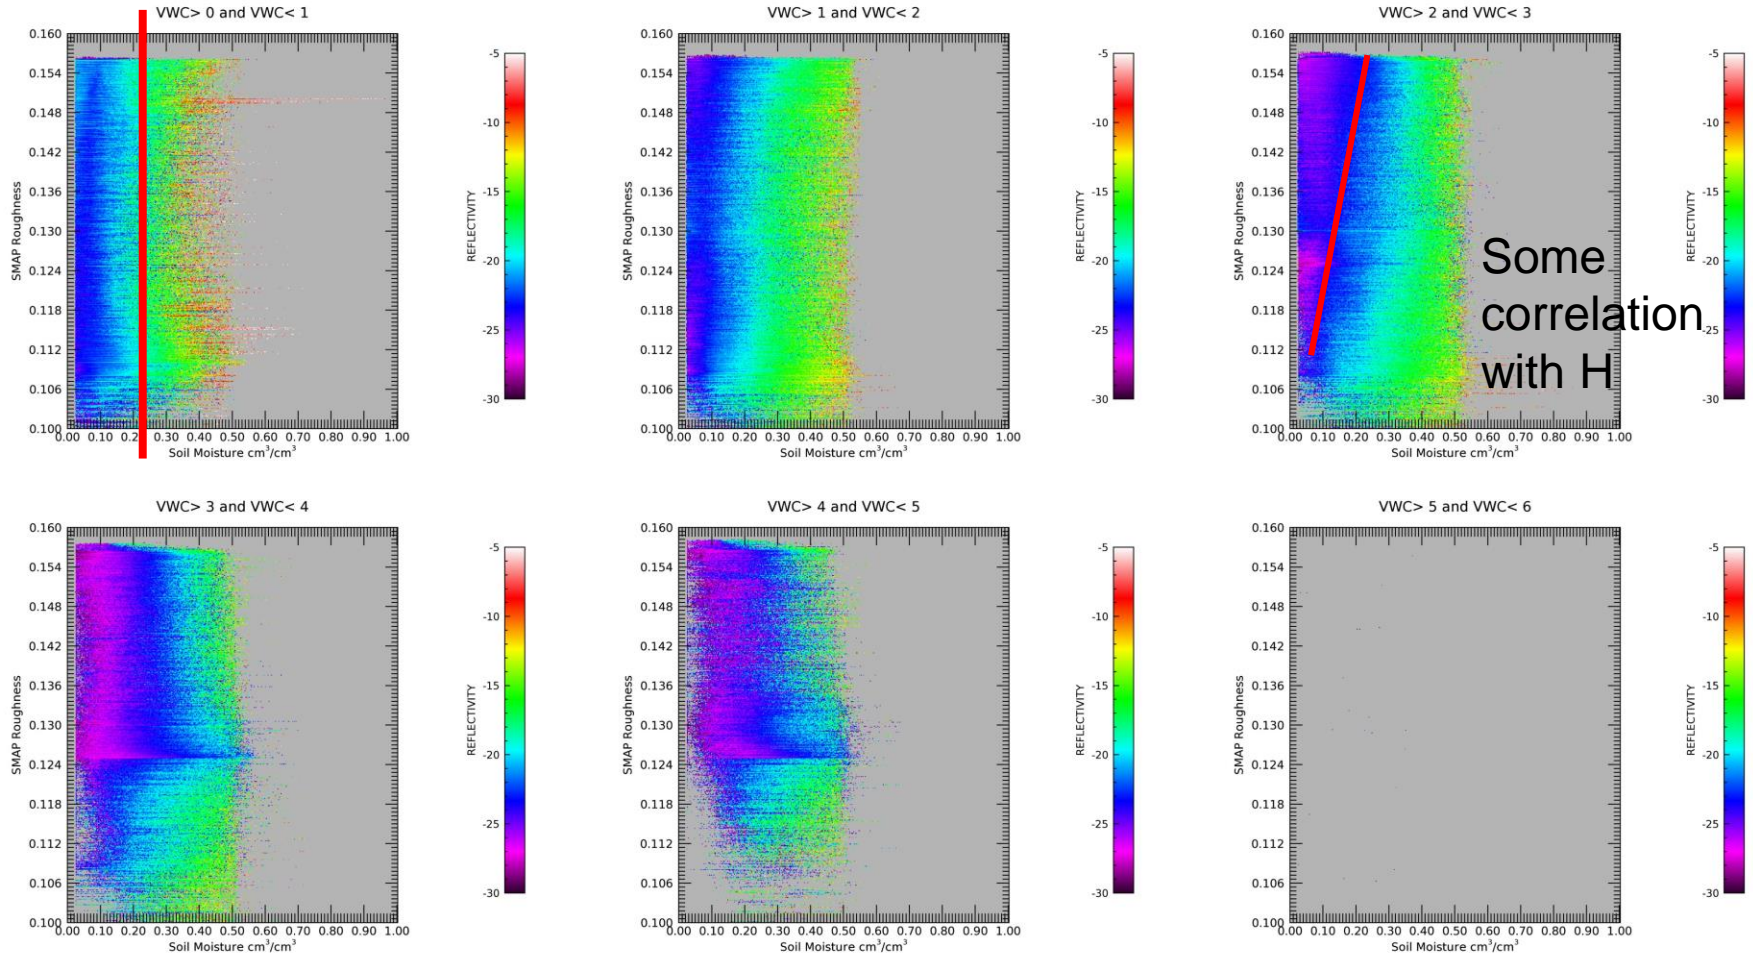

## Linear Model for NDVI tau appears reasonable

$$R_{\tau\theta} = -20 \log_{10}(e) \frac{VWC}{\cos\theta} b + R_{\theta}$$

	10-20	20-30	30-40	40-50	50-60	Average
$b$	0.17	0.17	0.17	0.15	0.11	0.15

# CYGNSS Reflectivity vs. SMAP SM & Baseline Surface Roughness Ancillary

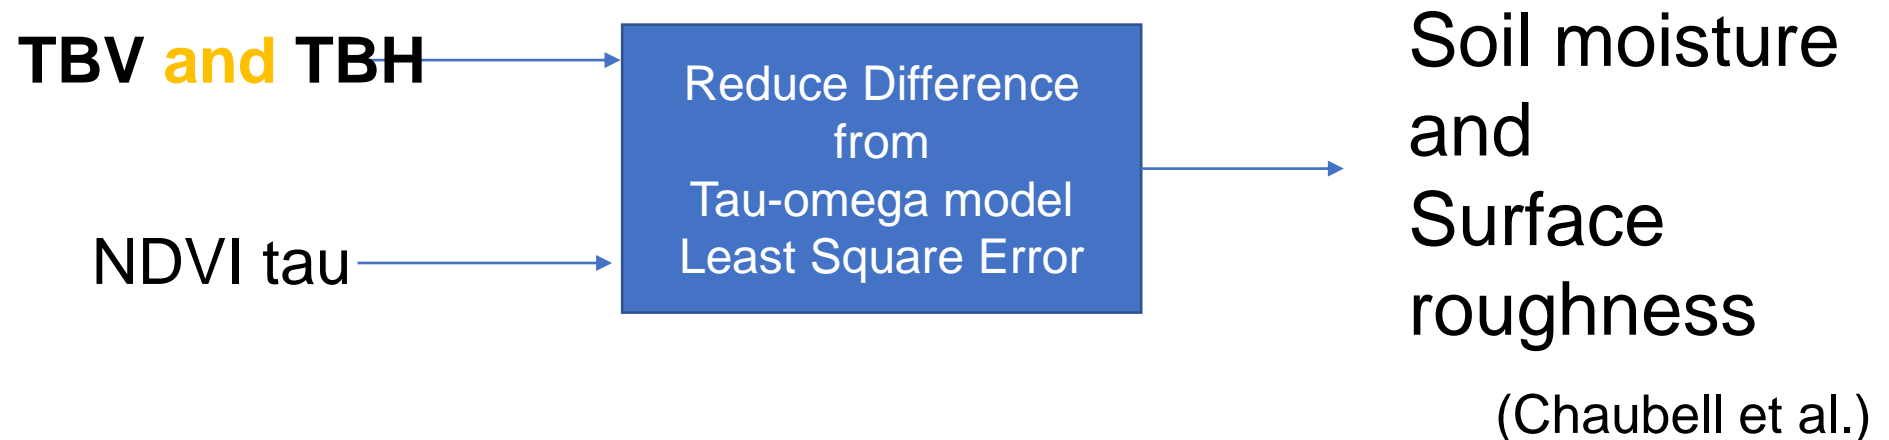

No correlation with SMAP baseline surface roughness

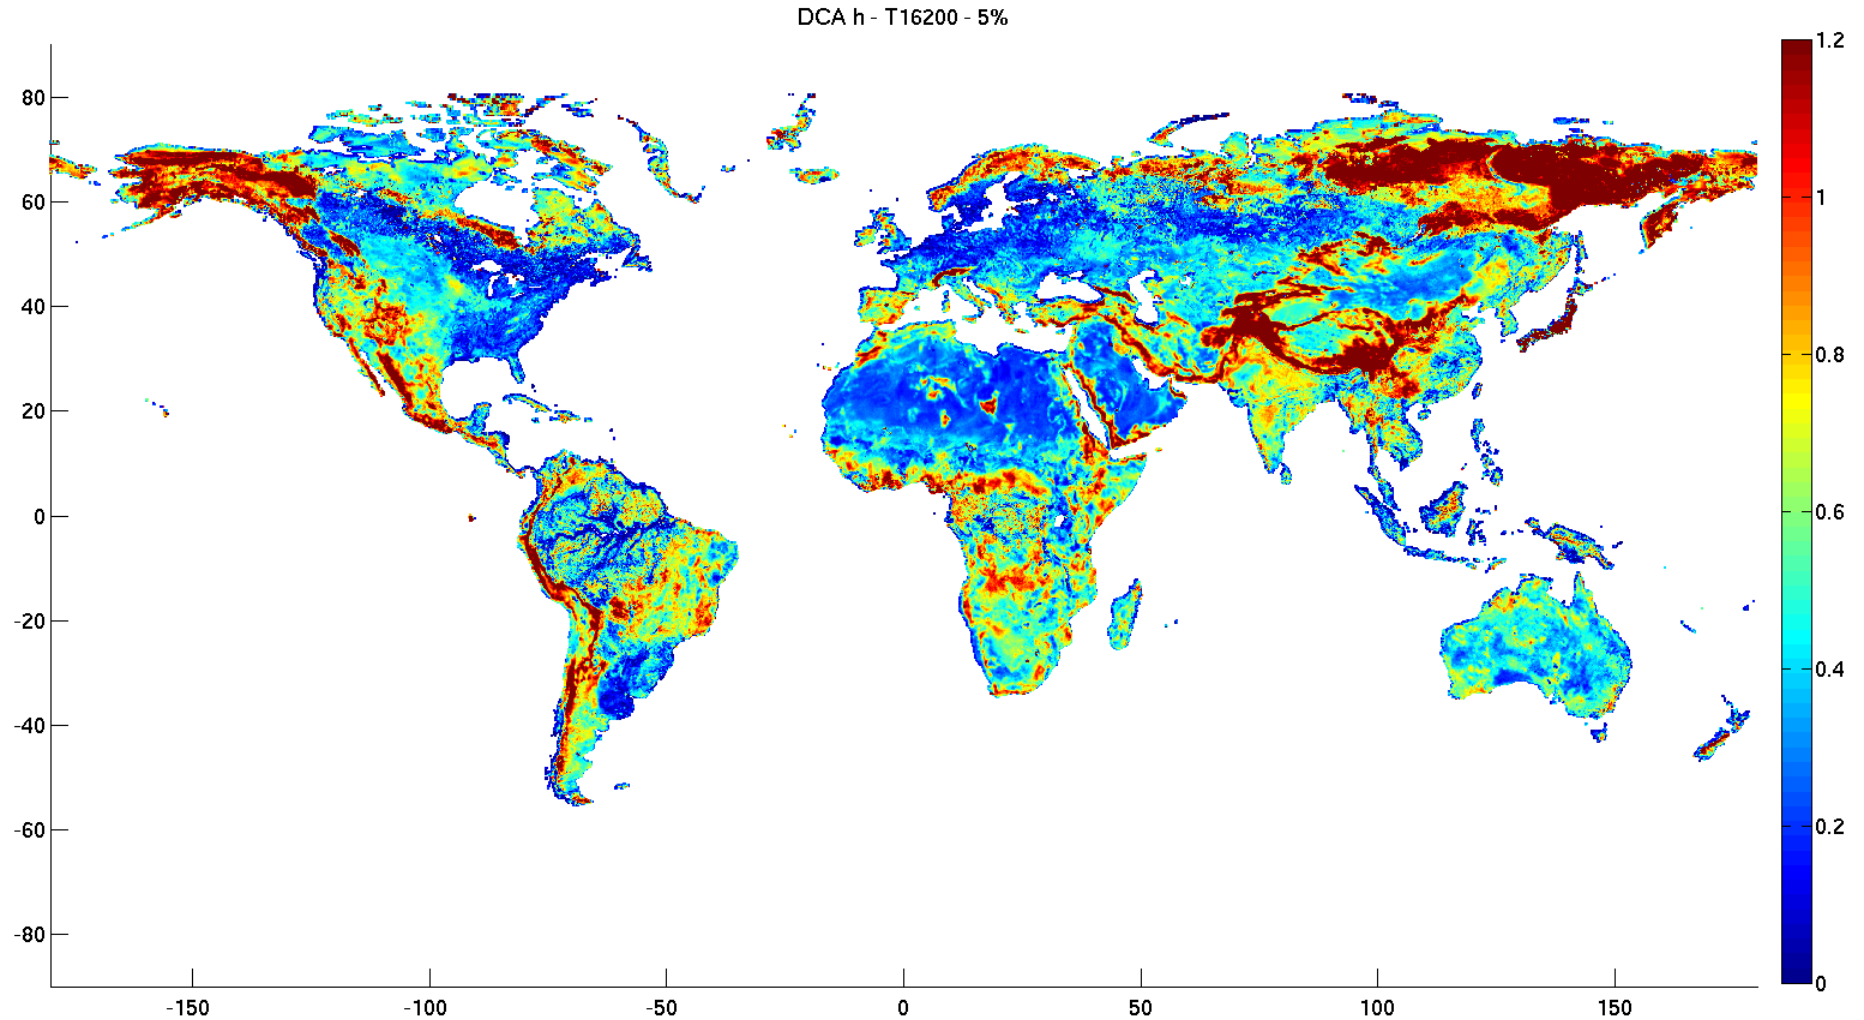

# Surface Roughness

## Derived from SMAP Dual-Pol Data

- Use Dual Channel Algorithm: Retrieved soil moisture and  $h$  by letting  $\tau = \text{NDVI } \tau$
- Include  $Q = 0.1771 * h$  to represent polarization mixing
- Averaged  $h$  map on 3 and 9 km grids (NDVI  $\tau$  threshold applied)
- Dual Channel Algorithm (DCA)

# Surface Roughness From SMAP Dual Channel Algorithm

# DCA Surface Roughness Example

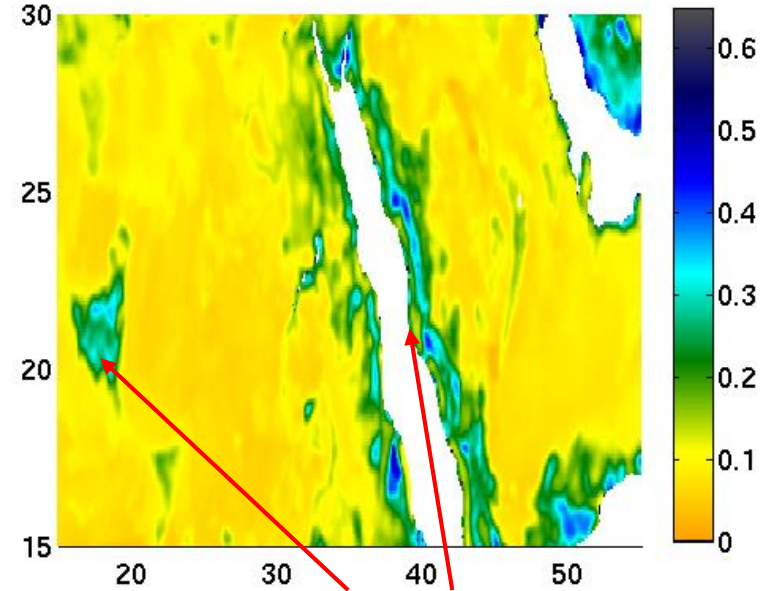

## SMAP soil moisture using DCA surface roughness

MDCA SM - T16300

## SMAP soil moisture using baseline surface roughness

DCA SM - R16020

Artifacts related to topography

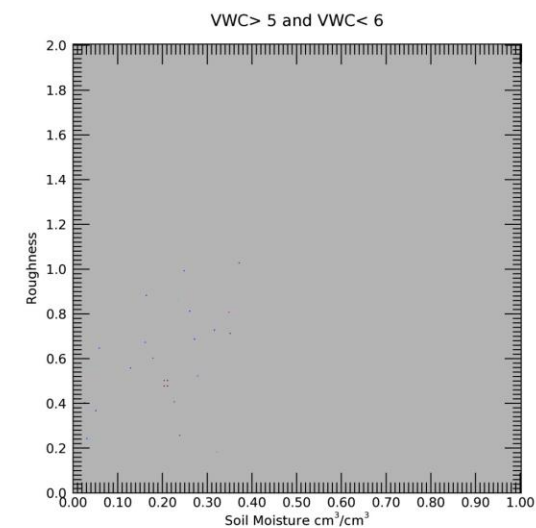

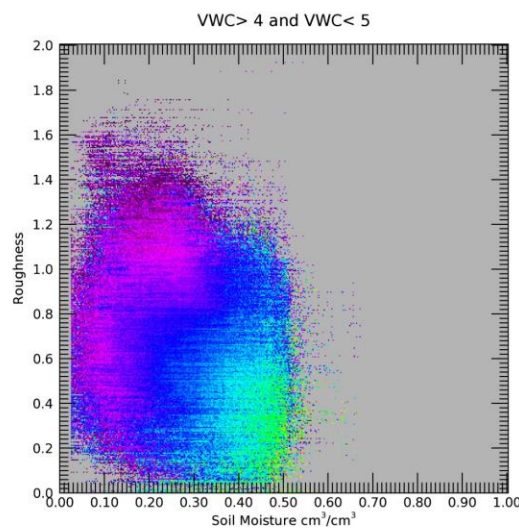

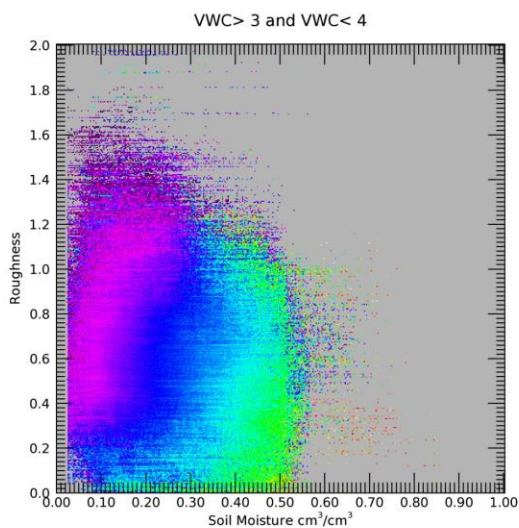

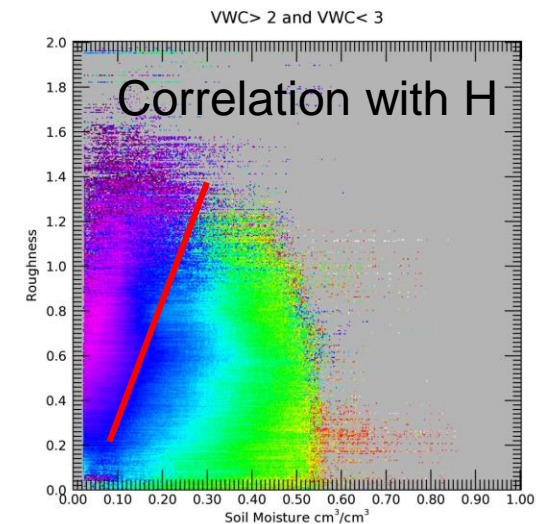

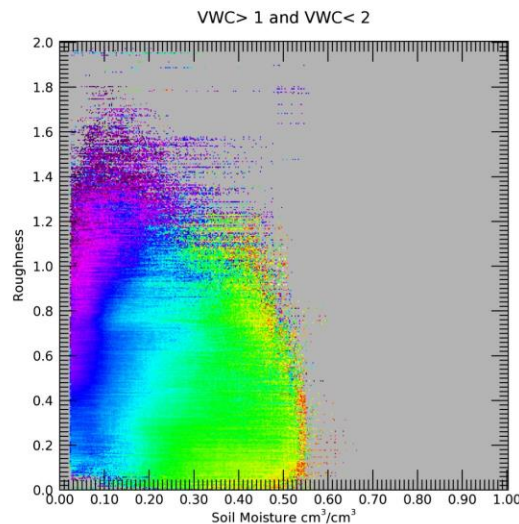

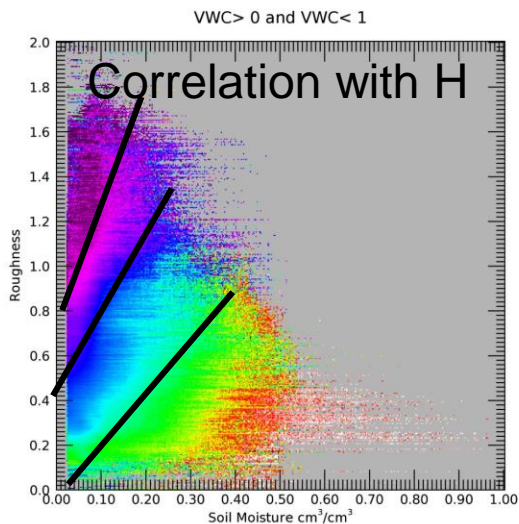

DCA Surface Roughness removes some artifacts due to topography from SMAP soil moisture retrieval

# CYGNSS Reflectivity vs. SMAP SM & DCA roughness (H)

Jet Propulsion Laboratory

# Dependence of Reflectivity on Surface Roughness

VEGETATION WATER CONTENT RANGE 0-1

$$R_{h\theta} = e^{-aH} R_{\theta}$$

$$R_{h\theta} = -10 \log_{10}(e)a H + R_{\theta}$$

Incidence Angle (deg)	Slope	a
15	-9.04	2.08
25	-10.78	2.48
35	-11.25	2.59
45	-11.23	2.59
55	-8.24	1.90

- No obvious dependence on incidence angle
  - Large scale random surface dominates?
- Linear dependence on h
- Non-Rayleigh – slope should be  $\sim -(2kh\cos\theta)^2$

# CYGNSS Reflectivity vs. SMAP SM

Compensation by SMAP soil moisture and roughness effects

$$\Delta R = R_{cygnss} - R_{h\theta}$$

$$R_{h\theta} = -10 \log_{10}(e) a H + R_{\theta}$$

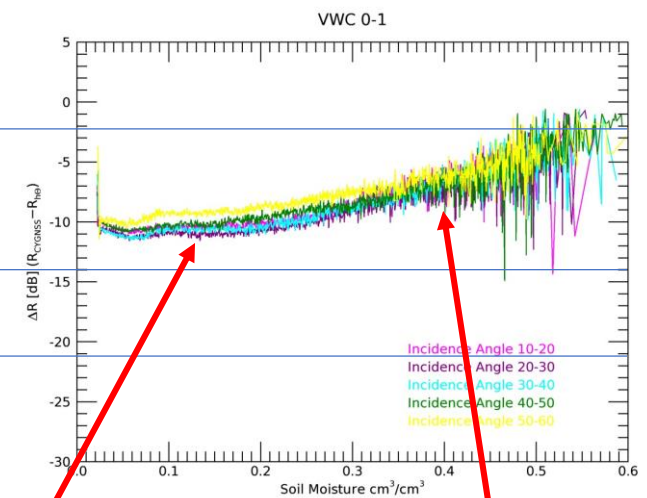

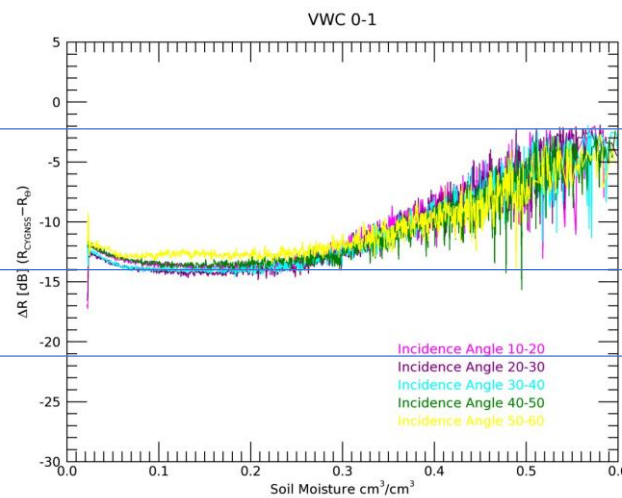

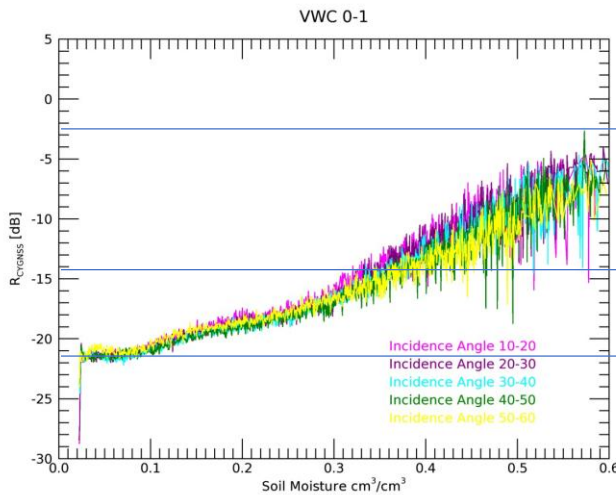

$a=2.3$

After compensation using SMAP soil moisture

$$\Delta R = R_{cygnss} - R_{\theta}$$

$R_{\theta}$ : Expected CYGNSS reflectivity using SMAP soil moisture and Mironov model

CYGNSS R

Reflectivity for soil moisture < 0.2 can be largely flattened by using dielectric and roughness models

There is about 7 dB increase wrt soil moisture in the residual for moisture > 0.2

# Summary

- Characteristics of CYGNSS reflectivity reflect the change of SMAP soil moisture and NDVI-derived optical depth ( $\tau$ ).
- SMAP baseline surface roughness is inconsistent with CYGNSS reflectivity.
- CYGNSS reflectivity is correlated with SMAP DCA surface roughness.
- CYGNSS dependence on soil moisture cannot be fully modeled by the Mironov dielectric model and empirical SMAP surface roughness.
  - There is 7 dB residual for wet soil ( $>0.2$  volumetric moisture).
